S Supporting Information

ABSTRACT: Carbon dioxide exhibits many of the qualities of an ideal reagent: it is nontoxic, plentiful, and inexpensive. Unlike other gaseous reagents, however, it has found limited use in enantioselective synthesis. Moreover, unprecedented is a tool that merges one of the simplest biological approaches to catalysis—Brønsted acid/base activation—with this abundant reagent. We describe a metal-free small molecule catalyst that achieves the three component reaction between a homoallylic alcohol, carbon dioxide, and an electrophilic source of iodine. Cyclic carbonates are formed enantioselectively.

The current global economic and environmental landscape has accelerated research into carbon dioxide (CO₂) capture and storage (CCS) technology across a broad range of chemical disciplines. The most notable advancements have been made in the areas of materials chemistry,¹ carbon storage engineering, and alkylamine-based “scrubbing” systems.² The threat of CO₂ accumulation as a greenhouse gas has motivated these sequestration strategies, but this gaseous reagent holds immense potential value as an abundant and nontoxic C1 building block³ for carbon–carbon bond formation and carbon–heteroatom functionalization reactions in chemical synthesis.^{4,5} Unfortunately, the underlying features that contribute to carbon dioxide’s low general toxicity and ease of handling render it relatively inert as a chemical reactant.⁶ This is punctuated by the contrasting abundance of enantioselective chemical reactions using hydrogen (H₂),⁷ oxygen (O₂),⁸ and even carbon monoxide (CO).⁹ Chemical technologies that preferentially form one handedness (enantiomer) of a chiral product have direct application to drug development and new materials. Despite the virtues of high temperature and/or pressure to address poor reactivity, transformations employing CO₂ as a reagent¹⁰ are typically limited to either Lewis basic substrates with sufficient nucleophilicity to react with the poorly electrophilic CO₂³ or metal-based reagents to increase the rate of CO₂ incorporation, often through a metal carboxylate intermediate (Figure 1A).^{11,12} We sought a reagent, ideally a catalyst, that could both overcome these barriers to reactivity and/or unfavorable equilibria while simultaneously controlling stereoselection; in essence, a catalyst that could stabilize a substrate–CO₂ adduct but still activate this adduct toward subsequent carbon–oxygen bond formation. Unprecedented is the use of a metal-free catalyst to stabilize the adduct of a weak nucleophile with CO₂, such as a carbonic acid–base complex, while effectively guiding it toward enantioselective

Figure 1. Enantioselective methods using CO₂ as a reagent, contrasting state-of-the-art metal-mediated reactions with this report of Brønsted acid/base catalysis.

carbon–oxygen bond formation. Metal-based systems include CO₂ insertion into activated epoxides generating almost exclusively five-membered cyclic carbonates, including enantioselective kinetic resolutions (Figure 1A).¹³ Additionally, Yamada has reported a silver(I)-based alcohol desymmetrization using CO₂ at high pressure to prepare five-membered cyclic carbonates.¹⁴

We posited that a properly balanced Brønsted acid/base bifunctional catalyst might lower the barrier to CO₂ incorporation and/or assist in the stabilization of the resulting adduct¹⁵ as a prelude to its use as an oxygen nucleophile in a subsequent enantioselective carbon–oxygen bond-forming step.¹⁶ If this could be achieved using a metal-free catalyst—an organocatalyst—the virtues of minimalism (symmetrical catalyst, low temperature, atmospheric pressure, near-neutral pH) would apply, suggesting broad impact. Here, we validate this design by the development of a carboxylation/alkene functionalization reaction of homoallylic alcohols to produce chiral cyclic carbonates.

Homoallylic alcohol **1a** became the basis for developing a tandem alcohol carboxylation–alkene iodocarbonation reaction due to the lower steric demand of a 1,1-disubstituted alkene. The standard reaction to which others are compared involved chilling (–20 °C) a toluene solution of homoallylic alcohol (**1a**, 0.4 M) prior to addition of *N*-iodosuccinimide (Table 1, entry 1) and CO₂ (balloon). These catalyst-free conditions returned the starting material following a 48 h reaction period. Compared to

^aCatalyst prepared as the 1:1 acid salt, except entry 21. ^bMS denotes molecular sieves 4A, employed at a concentration of 1 g/mmol relative to the alcohol. ^cIsolated yield. ^dEnantiomeric excess (ee) determined by HPLC using a chiral stationary phase. Reactions are 0.4 M toluene unless otherwise noted. ^eReaction temp = 0 °C. 3-Methyl-3-buten-1-ol was converted in 60% yield under identical conditions. ^f20 mol % catalyst employed. ^g5 mol % catalyst employed, with results analogous to those using 10 mol % catalyst.

an otherwise identical reaction, addition of a strong base (sodium hydride, Table 1, entry 2) delivered the desired cyclic carbonate, but in only 16% yield.¹⁷ Substitution of a more polar solvent (e.g., THF) for toluene increased the yield marginally (Table 1, entry 3). Based on precedence for Brønsted basic amines to react directly with CO₂ or CO₂/H₂O combined, several amine bases were examined (Table 1, entries 4–5) as well as hydrogen-bond donor/acceptor amines (e.g., TBD, Table 1, entry 6) in an attempt to accelerate the desired reaction.^{18,19} These extensive attempts generally provided three outcomes: (1) return of unreacted homoallylic alcohol, (2) formation of apparent iodoetherification products, or simply (3) low yields (<15%) of the desired carbonate. Similarly, good hydrogen-bond donors, such as TFA or thiourea 3²⁰ (Table 1, entries 7–8) failed to deliver any significant amount of carbonate.

Our ultimate goal was to explore the ability of a Brønsted acid/base combination to promote the reaction. Use of pyrrolidine-substituted bis(amidine) 7 (“PBAM”) resulted in an 18% yield of

2a, however the carbonate was formed in a promising 39% ee (Table 1, entry 9) at –20 °C. The analogous catalyst incorporating *trans*-stilbene diamine (“StilbPBAM” (8)) instead of *trans*-cyclohexane diamine provided the product in 33% yield and similar ee (36% ee, Table 1, entry 10). It was noted in these early experiments that the addition of molecular sieves (MS 4A) resulted in more consistent reactions as judged by conversion and/or yield (Table 1, entry 11). In reactions without sieves, formation of a precipitate appeared to correlate with lower yields and varying enantioselectivity (particularly with free base (7 or 8; *vide infra*). Exploration of strong Brønsted acid additives (1:1 ligand:acid) led to moderate differences in enantioselection (Table 1, entries 12–15), with catalyst complex 8·HNTf₂ providing product with 91% ee (Table 1, entry 15). Some sensitivity of both yield and selectivity to concentration was noted,²¹ with lower concentrations leading to depressed yield and selectivity (Table 1, entries 16–17). We reinvestigated several achiral amine bases under these optimized conditions, with only marginal improvement in yield (Table 1, entries 18–21). Attempts were also made to simulate the Brønsted acid/base character of catalyst 8·HNTf₂ using monobasic amines in combination with varying amounts of Brønsted acid (e.g., Table 1, entry 21), none resulting in significant improvement of yield. Collectively, these results suggest an underlying order to the hydrogen-bonding network in the key selectivity-determining step, if not unique reactivity associated with the proper positioning of a Brønsted acid and base in the same molecule, in this CO₂-fixation reaction.

Application of conditions optimized for homoallylic alcohol 1a to a range of similar substrates is outlined in Table 2. α -Substituted styrene derivatives were scrutinized using the mild conditions developed (2a–m, Table 2). Nominal substitution of the aromatic ring led to equally positive outcomes, with 2a–c formed in 91–95% ee and high chemical yield (82–96% yield) (Table 2, entries 1, 3–5). Substitution near the alkene was not tolerated, as no substrate conversion was observed to produce 2d or 2e (Table 2, entries 6–7). Increasing the reaction temperature to 0 °C led to complex mixtures suggestive of competing intermolecular iodoetherification. However, a β -naphthyl-substituted alkene led to good enantioselection and yield (2f, 90% ee, 88% yield) (Table 2, entry 8). Anisole derivatives (*meta*- and *para*-substituted) provided generally good enantioselectivity (80–90% ee) and higher chemical yield (97%, 2h), but lower yield for 2g (Table 2, entries 9–10). Halogen-substituted arenes led to a range of results, mostly related to reactivity, while selectivity remained high; some reached only partial conversion despite extended reaction times. Halogen substitution *meta* and *para* to the alkene provided consistently good enantioselection (87–90% ee) (Table 2, entries 11–14). Reactivity varied greatly among 2i–l, however, and suggested that the alkene nucleophilicity might be a key determinant of reactivity. Carbonate 2m was produced in nearly quantitative yield and 91% ee (Table 2, entry 15).

Alkenes bearing aliphatic substituents are often regarded as challenging substrates in stereoselective difunctionalization reactions.²² 3-Alkyl butenols were prepared and converted to carbonates 2n–p with promising levels of enantioselectivity (up to 74% ee) (Table 2, entries 16–18). Iodocarbonate 2o, derived from the sterically unencumbered 3-methyl-but-3-ene-1-ol, a widely available isoprenyl feedstock, formed in a moderate 68% ee. Although not a focus of these investigations, allylic alcohols reacted sluggishly but exhibited good yield and lower enantioselection. In an effort to probe the adaptation of this

^aEnantiomeric excess (ee) determined by HPLC using a chiral stationary phase. Reactions are 0.4 M in toluene. Isolated yields are listed. See SI for complete experimental details. Absolute configuration for 2a assigned using X-ray analysis, remaining examples assigned by analogy. ^b6.8 mmol (1.0 g) substrate was employed under the optimized conditions (1 atm CO₂) utilizing 3.0 mol % catalyst for 48 h. ^c10 mol % catalyst loading. ^dReaction temperature was −50 °C. ^eIt was noted that purified 2g was prone to decomposition.

method to larger amounts, a gram-scale experiment using 3 mol % catalyst led to the carbonate in 89% ee and 79% yield (Table 2, entry 2). Finally, spirocyclic carbonate 2q was prepared from the corresponding trisubstituted alkene in moderate yield (63%) and encouraging enantioselection (69% ee) (Scheme 1).

Scheme 1. Iodocarbonation of a Trisubstituted Alkene

Several experimental observations are worth mentioning in addition to the trends summarized above. Foremost among these, use of a CO₂ balloon attached to a degassed reaction established that the steady-state CO₂ concentration is significant in chilled toluene and could be reached within 40 min; far shorter than the time to complete conversion to carbonate (monitored by in situ IR). The rate of CO₂ absorption was affected insignificantly by most every factor examined, including temperature, the presence of MS 4A, and stirring rate. The correlation between high chemical yield and molecular sieves can be explained by the formation of a complex between the catalyst, adventitious water, and CO₂, which we hypothesize to be the carbonic acid salt (Figure 2).²³ This complex precipitates from the reaction mixture when using 8•HNTf₂, but its formation

**Figure 2. Catalyst Inactivation Pathway and Its Recovery Using MS 4A.**

appears reversible, reverting to active catalyst when a desiccant (MS 4A) and dry gas (argon) are added. Although a noncovalent complex is hypothesized in our work, some nucleophilic amines can form a covalent adduct with CO₂.²⁴ When not in competition with water, the alcohol substrate can entrain CO₂, forming an intermediate and transient alkyl carbonic acid salt with the bifunctional catalyst. This intermediate, in reaction with NIS, forms a complex which then collapses to the cyclic carbonate either stepwise or directly.²⁵

While cyclic carbonates are valuable in their own right²⁶ and are prepared here using CO₂ as a phosgene surrogate, Scheme 2

Scheme 2. Conversions of Carbonate Products^a

^aConservation of ee observed in all cases.

details several notable transformations. First, reduction by stannane provided carbonate 9 in 86% yield when applied to iodocarbonate 2a. Straightforward carbonate hydrolysis with a basic resin in methanol led to the versatile epoxide 10. This is particularly significant from the viewpoint that CO₂ is effectively used as an equivalent to epoxidation, which normally requires an electrophilic source of oxygen (e.g., a peracid or dioxirane). Full reduction employing a stronger reducing agent (LiAlH₄) leads to tertiary alcohol 11 in 71% yield. This CO₂ fixation method therefore offers a simple two step equivalent to metal-free oxidations of homoallylic alcohols,²⁷ for which CO₂ is converted to either dialkyl carbonate or methanol.

In summary, a mild and operationally straightforward CO₂ fixation reaction has been developed using a dual Brønsted acid/base catalyst that presents hydrogen-bond donor and acceptor functionality to activate and orient substrates in an enantioselective reaction. This metal-free method employs relatively weak nucleophiles (homoallylic alcohols) in the CO₂ fixation step, generating transient acids that add to an alkene in combination with *N*-iodosuccinimide. The catalysts deployed here use the virtues of Brønsted acid/base activation alone to achieve highly enantioselective carbonate synthesis.²⁸ From a different viewpoint, this CO₂ fixation method circumvents approaches dependent on phosgene²⁹ as a source of carbonate protecting group for 1,3-diol prepared through stereoselective synthesis. Numerous enantioenriched small molecules might be prepared using CO₂ as a source for carbon–oxygen bond formation.

- (28) It is worth noting the magnesium-dependent enzyme ribulose-1,5-bisphosphate carboxylase/oxygenase (RuBisCO). RuBisCO incorporates CO₂ through carbon-carbon bond formation into glucose precursors. Berry, J. A.; Lorimer, G. H.; Pierce, J.; Seemann, J. R.; Meek, J.; Freas, S. *Proc. Natl. Acad. Sci. U. S. A.* **1987**, *84*, 734.
